1 Title of the Project

Comparative Analysis of Deep Learning Architectures (LSTM, CNN, and Transformers) for NEPSE Stock Price Prediction.

2 Introduction

The concept of machine learning has become a critical aspect of the modern artificial intelligence when the computational systems can identify patterns in the collections of the data and make the predictions that are not directly related to a set of rules that are personally developed. Within the task of analysis, the methods find extensive use in classification, regression, clustering and forecasting of sequential data. This has been enabled by the escalating availability of big data sets and the surge in computing capability which has enabled machine learning models to disclose hidden patterns in complicated information that has made it extremely significant in numerous industries such as healthcare, finance, transportation, manufacturing and e-commerce (Hapuarachchi, 2025).

Financial markets are highly dynamic in terms of behavior with high amount of uncertainty, noise and high non-linearities particularly in stock exchanges. It was extremely hard to predict, since the dynamics of the stock prices are predetermined but the interplay of the economic indicators, the events in the political sphere, the sentiment and investor psychology of the market, which is very difficult to forecast. Thus, price classification of stock has been one of the most challenging questions of machine learning in cases when there is a significant presence of very sensitive monetary time series information. Nonetheless, predictable and highly accurate predictive models can be of excellent importance to investors, financial institutions, and regulators since it allows competent decision-making (Seetharaman, 2021).

This study aims at developing a conceptual AI predictive stock price model of NEPSE (Nepal Stock Exchange) based on three common deep learning architectures: Long Short-Term Memory (LSTM) networks (Wenjie Lu, 2020), 1D Convolutional Neural Networks (CNN), and Transformer architectures. These are three angles of sequence modelling, which can be used to compare the performance of forecasting.

NEPSE is a market that is emerging and there is less research conducted on data-driven forecasting. It presents a perfect problem area since computation of smart forecasting models may lead to better decision-making of the Nepali financial system

2.1 Evolution from Milestone 1: Classification to Regression

Following the presentation of Milestone 1, and feedbacks on the same as provided by my tutor Mr. Binod Bhattarai, an in-depth re-consideration process was undertaken. It was found that the accuracy of classification was decent (around 55-60 percent), but the method did not make use of the abundant numerical data that financial time series data provides.

Based on this feedback, the methodology was radically changed to regression where the models forecast not where the direction moves but what the actual next-day closing price will be.

2.2 Key Deliverables:

- Full processing pipeline of prep and processing of NEPSE stock data.
- Execution of experimentation of 3 time-series prediction deep-learning structures.
- Severe performance appraisal and several metrics.
- Comparison of all the approaches with their advantages and drawbacks.
- The evidence-based recommendations.
- Full codebase including implementations reproducible and printed hyperparameters.

3 Background and literature review

3.1 NEPSE Stock Market Domain

Nepal Stock Exchange (NEPSE) is a vibrant financial market where share of various companies such as commercial banks, insurance companies, hydropower, telecommunications and manufacturing companies are traded.

NEPSE also includes a list of commercial banks, insurance companies, hydropower projects, telecom operators as well as manufacturing industry

Dataset Characteristics:

In this study, 17 commercial banks which were listed in NEPSE were selected since:

- The commercial banks possess the oldest and most complete trading histories.
- Attention to a single sector also minimizes confounding variables in an industry.
- Banking stocks, constitute one of the most heavily traded stocks on NEPSE.

Common historical price data: Historical prices are generally treated as a data set, describing the market in terms of a number of indicators, such as:

- Open price
- High price
- Low price
- Close price
- Percentage change
- Traded quantity
- Traded amount

It is an advantage that structured CSV data on NEPSE companies are available as a result of which it is possible to experiment with AI algorithms in prediction.

3.2 Time-Series Forecasting in AI

In time-series analysis, future data points are projected by learning temporal relationships from historical ordered data. Stock prices are a typical example, where the order of data

points is crucial. Traditional statistical models have limitations in capturing complex non-linear patterns, motivating the use of deep learning.

3.3 Deep Learning Approaches for Forecasting Financial Market Data

Deep learning models excel at feature extraction, non-linear pattern learning, and sequence modelling. The following architectures are widely used for financial forecasting:

3.3.1 Long Short-Term Memory (LSTM) Networks

Long Short-Term Memory networks extend the recurrent neural network framework by introducing memory cells and gating mechanisms that regulate information flow, allowing the model to retain relevant information over long temporal sequences.

Strengths:

- Good at learning temporal relationships
- Handles vanishing gradients
- Widely used for stock prediction

3.3.2 Convolutional Neural Networks (1D CNN) for Time-Series

Though commonly used in image processing, 1D CNNs can detect spatial/temporal patterns in sequential data.

Strengths:

- Captures local patterns
- Faster to train than LSTM
- Effective for short-term prediction windows

3.3.3 Transformer Models

Transformers use attention-based mechanisms rather than recurrent structures, which helps the model identify influential time steps and understand long-range patterns in sequential data.

Strengths:

- State-of-the-art performance in many time-series tasks
- Parallel training
- Works well with multi-series datasets

3.4 Review of Existing Literature

The models used in research in the field of global stock forecasting included LSTM, GRU, CNN, and Transformer-based models.

3.4.1 Study 1: Forecasting NEPSE Index Prices Using Deep Learning Techniques

- **Key Finding:** The LSTM model architecture has offered the greatest performance regarding the conventional evaluation measures, such as Root Mean Square Error (RMSE) and Mean Absolute Percentage Error (MAPE), in comparison to the GRU and CNN in processing the non-linear, complex, and volatile NEPSE time series data (Nawa Raj Pokhrel, 2022)

3.4.2 Study 2: Financial Market Prediction Employing Long Short-Term Memory Networks

- **Key Findings:** LSTM was extremely efficient in comparison with conventional ML (Random Forests, DNNs) because it was able to identify long-term correlations. Normalization (preprocessing, sequence formation) was important (Thomas Fischer, 2018).

3.4.3 Study 3: Comparative Analysis of RNN, LSTM, BiLSTM, GRU, and Transformer Models for Financial Forecasting

- **Key Findings:** Transformer demonstrated better accuracy and more effective convergence to all setting of RNN (LSTM, GRU), which proved the advantage of the self-attention mechanism (T.O. Kehinde, 2023).

3.4.4 Study 4: Stock Prediction Based on Transformer Model

- **Key Findings:** The combination of the Transformer and LASSO regularization

performed significantly better in the context of robustness and had low MAPE, which indicates that feature engineering is needed to the real NEPSE forecast (Ekanta Rai, 2025).

3.4.5 Study 5: A Deep Neural Network-Based Stock Trading System Incorporating Evolutionary Optimized Technical Analysis Parameters

- **Key Findings:** CNN was more effective in high-frequency trading (speed). Predictions by LSTM were more stable in longer investment horizons (Omer Berat Sezera, 2017).

These studies show:

- The sequential memory is well recalled by LSTM.
- CNN is effective in the extraction of patterns.
- Both due to attention mechanisms tend to be outperformed by transformers.
- In Nepal, there is a paucity of academic literature on computational stock prediction, which creates an opportunity of AI-based stock forecast to generate value..

3.5 Problem Statement

Prediction of stock prices in the emerging stock markets like NEPSE are so difficult to predict because the data is complicated, the markets are volatile and systematic comparative study using advanced deep learning architecture is not available. Moreover, minimal literature is done on the use of the state-of-the-art models like Transformers on NEPSE data and it is not known whether certain algorithms are more effective in this market environment.

In this paper, the primary issue fashioned is the following issue:

- What is the comparison of LSTM with CNN and Transformer model in their ability to predict next-day stock price of the companies listed on NEPSE?

With the solution to this issue, the study will result in evidence-based recommendations of selecting appropriate deep learning-based architectures in predicting stock prices in future markets, which will aid in better decision making.

3.6 Research Questions / Objectives

3.6.1 Research Questions

1. Which deep learning architecture (LSTM, CNN or Transformer) has the most accurate prediction accuracy of NEPSE Stock Price Forecasting?
2. How are the preprocessing steps such as data normalization, sequence generation and feature encoding affecting the performance of each model?
3. What are the computation efficiency differences between the LSTM, the CNN, and the Transformer model in terms of time of training and the number of resources needed?
4. Which are the most suitable evaluation metrics in predicting financial time series data in real-world scenarios?

3.6.2 Research Objectives

1. Develop a unified multi-company dataset by incorporating historical stock data from NEPSE-listed companies.
2. Design and implement preprocessing pipelines such as data cleaning, feature scaling and sequence generation suitable for deep learning models.
3. Develop three architectures for deep learning: LSTM, CNN and Transformer which are optimized for time series regression using the same input data to compare the three architectures fairly.
4. Train all the three models with the same hyperparameters, training protocols and validation strategies.
5. Evaluate model performance using several metrics and visualize comparison results.
6. Issue evidence-based suggestions for algorithm choice and provide evidence for selecting sensitive, efficient, and implementation feasible for algorithms.

4 Solution

4.1 Proposed Solution Overview

This study, regression structure is applied in a structured way in which it is supervised to estimate the forthcoming closing price on a day-by-day basis using past 60 day sequence data. There are seven key stages of solution pipeline:

- Data Collection: Information on aggregate historical trading of 17 NEPSE commercial banks.
- Feature Engineering: Choose best features.
- Sequence Generating: Generate overlapping 60-day windows and targets.
- Temporal Splitting: Segregate data based on time in order to avoid information leakage in the future.
- Normalization: Direct normalization of features and targets.
- Model Training To train three architectures using the same protocols.
- Performance: Comparison of multiple regression metrics.

4.1.1 Proposed AI Algorithms

Algorithm	Architecture Type	Reason for Selection
LSTM	Recurrent Neural Network (Deep Learning)	LSTM Recurrent Neural Network (Deep Learning) The LSTM networks are intended to deal with moving data over time, and its efficacy to capture lasting time-based associations through memory cells and gating apparatuses. They meet the vanishing gradient challenge of standard RNNs as well as have already proved performance of great financial time-series forecasting by learning fundamental historical patterns of prices even after long durations (Thomas Fischer, 2018).

CNN (1D)	Convolutional Neural Network (Deep Learning)	CNN (1D) Convolutional Neural Network (Deep Learning) The CNNs are one-dimensional convolutions, and they are efficient to extract local time series information temporal patterns. They can be used to find fast growing and declining trends in the market and produce faster training and computation performance than recurrent models (Avinash, 2021).
Transformer	Attention-based Neural Network (Deep Learning)	Transformer Attention-based Neural Network (Deep Learning) Transformers are based on self-attention to systematically model both short-term and long-term dependencies, without the use of recurrence. Their parallel processing nature enhances training speed and more recent research indicates that they are better than traditional architecture in time-series predictions tasks (Rogerio Pereira dos Santos, 2025).

Table 1: Proposed Algorithms

4.1.2 Dataset Description

- **Dataset Source:** Historical stock price data collected from Nepal Stock Exchange (NEPSE) official records made publicly available via GitHub repository. The repository is continuously updated using automated web-scraping techniques to reflect daily market activity.
- **Type:** Time-series financial dataset containing daily stock trading information.
- **Instances:** Each instance represents one trading day for a listed stock. The dataset spans multiple years with new records appended on each trading day.
- **Features:** The dataset used in this study includes the following variables:
 - **published_date:** published_date: Date of each trading session.
 - **open:** The price of the stock when the trading day opens.
 - **high:** This is the highest price at which the trading session moved.
 - **low** The lowest price in the session.

- close: The market close price.
 - per_change: the change of the closing price in percentage with respect to the previous trading day.
 - quantity traded: Total number of shares traded.
 - traded amount: Monetary amount of trading amount of shares.
 - company id: Company identifier.
- Engineered Features:

First, extensive technical indicators were developed using raw information in the field of trading. These indicators include trend, momentum, volatility, volume and price based indicators. The prediction target was determined by the next-day closing price.

It was demonstrated that the predictive performance was not enhanced by the technical indicators through experimental means. The more the input features included, the greater the noise, overfitting and more time was needed to train and the prediction was always less accurate. A small representation of features produced the best performance in all the models thus the following features were finalized:

 - Input Features:
 - Historical Closing Price (60-day sequence)
 - Momentum (Percentage Change)
 - Learned vector representations for each of 17 banks(Company Embeddings)
 - Target Variable
 - Next-Day Closing Price
 - Training Set: 80% temporal split (39,632 sequences, ~76.2%)
 - Test Set: 20% temporal split (12,411 sequences, ~23.8%)
 - Missing Values: The dataset contains occasional missing values which are handled during the preprocessing stage using appropriate techniques.

4.2 Pseudocode

4.2.1 Dataset Creation and Sequence Generation

BEGIN DataPreparation

 // Load and combine data

 Load 17 commercial bank CSV files

 Add company identifiers

 Merge into single dataset

 Sort by company and date

 // Feature engineering

 Calculate momentum as percentage change

 Fill missing values with zero

 // Create sequences per company

 FOR each company

 Create 60-day sliding windows

 Each sequence contains close price and momentum

 Target is next day closing price

 END FOR

 // Temporal train-test split

 Split data at 80% cutoff date

 Create training set (76.2% of sequences)

 Create test set (23.8% of sequences)

 // Feature scaling

Fit MinMaxScaler on training targets

Transform both training and test targets

Fit StandardScaler on training features

Transform both training and test features

// Create data loaders

Create PyTorch datasets with sequences

Create batched data loaders (batch size 32)

RETURN train_loader, test_loader, scalers

END

4.2.2 LSTM Model

```
BEGIN LSTMModel
```

```
// Build model architecture
```

```
Create company embedding layer (17 companies to size 4)
```

```
Add LSTM layer with 50 hidden units
```

```
Add fully connected layer combining LSTM and embedding
```

```
// Forward pass
```

```
Process sequence through LSTM
```

```
Extract last time step features
```

```
Get company-specific embedding
```

```
Concatenate LSTM output with embedding
```

```
Generate price prediction
```

```
// Configure training
```

```
Set optimizer to Adam with learning rate 0.001
```

```
Set loss function to MSE
```

```
Configure early stopping with patience 15
```

```
Create validation split (90/10)
```

```
// Train model
```

```
WHILE training not complete
```

```
    Process batch of training data
```

```
    Calculate prediction error
```

```
    Update model weights
```

```
    Check validation performance
```

```
    IF validation stops improving THEN
        Stop training
    END IF
END WHILE

// Return trained model
Load best model checkpoint
RETURN trained model
END
```

4.2.3 CNN Model

BEGIN CNNModel

// Build model architecture

Create company embedding layer (17 companies to size 4)

Add convolutional layers with kernel sizes 3

Add max pooling layers

Add fully connected layers with dropout

// Forward pass

Transpose input for convolution

Apply convolutional layers with ReLU

Apply pooling layers

Flatten CNN features

Get company-specific embedding

Concatenate CNN output with embedding

Generate price prediction through FC layers

// Configure training

Set optimizer to Adam with learning rate 0.001

Set loss function to MSE

Configure early stopping with patience 15

// Train model

WHILE training not complete

 Process batch of training data

 Calculate prediction error

```
    Update model weights
    Check validation performance
    IF validation stops improving THEN
        Stop training
    END IF
END WHILE

RETURN trained model
END
```

4.2.4 Transformer Model

BEGIN TransformerModel

// Build model architecture

Create company embedding layer (17 companies to size 4)

Add input projection layer (2 features to 32 dimensions)

Add transformer encoder (2 layers, 4 attention heads)

Add fully connected output layers

// Forward pass

Project input features to higher dimensions

Process through transformer encoder layers

Apply global average pooling

Get company-specific embedding

Concatenate transformer output with embedding

Generate price prediction

// Configure training

Set optimizer to Adam with learning rate 0.001

Set loss function to MSE

Configure early stopping with patience 15

// Train model

WHILE training not complete

 Process batch of training data

 Calculate prediction error

 Update model weights

 Check validation performance

 IF validation stops improving THEN

 Stop training

 END IF

END WHILE

```
    RETURN trained model  
END
```

4.2.5 Model Evaluation

```
BEGIN ModelEvaluation  
    // Evaluate each model  
    FOR each model (LSTM, CNN, Transformer)  
        Generate predictions on test set  
        Inverse transform to original price scale  
        Calculate RMSE (root mean squared error)  
        Calculate MAE (mean absolute error)  
        Calculate R-squared score  
        Calculate MAPE (mean absolute percentage error)  
    END FOR  
  
    // Compare results  
    Create results table with all metrics  
    Identify best model by lowest RMSE  
  
    // Visualize performance  
    Plot predictions vs actual prices  
    Plot metric comparison charts  
    Plot training history curves  
  
    RETURN comparison results and best model  
END
```

4.3 Diagrammatic Representation

4.4 Explanation of the development process

4.4.1 Development Workflow

4.4.1.1 Setup and Exploration

- Configured Google Colab environment
- Loaded and inspected 17 commercial bank datasets
- Analyzed data quality, completeness, and distribution
- Created initial exploratory visualizations
- Set random seeds (42) for reproducibility

4.4.1.2 Data Preprocessing

4.4.1.2.1 Dataset Combination:

- Merged 17 individual bank datasets into unified DataFrame
- Added company_id column to maintain bank identity
- Sorted chronologically by (company_id, published_date)
- Final combined dataset: 53,063 rows × 10 columns

4.4.1.2.2 Feature Engineering:

- Feature 1 (Close Price): Direct closing price values
- Feature 2 (Momentum): Percentage change

4.4.1.2.3 Company Encoding:

- Created company-to-ID mapping: {ADBL: 0, CZBIL: 1, ..., SCB: 16}
- Total unique companies: 17
- Encoded as integers for embedding layer compatibility

4.4.1.2.4 Sequence Generation:

- Implemented 60-day sliding window approach
- Generated sequences per company to prevent cross-contamination
- Each sequence (60 days)
- Target: Next-day closing price (day 61)

4.4.1.2.5 Temporal Split:

- Calculated cutoff date: 80% of (max_date - min_date)
- Training set: 39,632 sequences (76.2%) before cutoff
- Test set: 12,411 sequences (23.8%) after cutoff
- This ensures no future information leaks into training

Regression Dataset Preparation

This notebook prepares the combined dataset for regression analysis by merging all commercial bank CSV files into a single dataset.

Purpose: Create a unified dataset from individual bank stock data files for training regression models.

Output: `combined_banks_dataset.csv` - A merged dataset containing all commercial bank stock data.

1. Import Required Libraries

Import necessary Python libraries for data manipulation and file operations.

```

import pandas as pd
import glob
import os

print("Libraries imported successfully!")

```

[11] Libraries imported successfully!

2. Locate Commercial Bank Data Files

Identify all CSV files in the commercial-banks directory containing individual bank stock data.

```

# Define data directory
DATA_DIR = "commercial-banks/"

# Find all CSV files
csv_files = glob.glob(os.path.join(DATA_DIR, "*.csv"))

print(f"Found {len(csv_files)} bank CSV files:")
for file in csv_files:
    bank_name = os.path.basename(file)
    print(f" - {bank_name}")

```

[12] Found 17 bank CSV files:

- SBL.csv
- NICA.csv
- PCBL.csv
- PRVU.csv
- EBL.csv
- GBIME.csv
- CZBIL.csv
- KBL.csv
- MBL.csv
- HBL.csv
- SBL.csv
- SANIMA.csv
- NABIL.csv
- ADBL.csv
- SBI.csv
- NBL.csv
- NMB.csv

3. Load and Process Individual Bank Data

Load each bank's CSV file and add a company identifier to distinguish between different banks.

Figure 8: Locating commercial banks data files

3. Load and Process Individual Bank Data

Load each bank's CSV file and add a company identifier to distinguish between different banks.

```

Total dataframes loaded: 17

4. Combine All Bank Data

Merge all individual bank dataframes into a single combined dataset.

```

# Concatenate all dataframes
data = pd.concat(df_list, ignore_index=True)

print(f"Combined dataset created with {len(data)} total rows")
print(f"Dataset shape: {data.shape}")
print(f"Columns: {list(data.columns)}")

```

(14)

... Combined dataset created with 53,863 total rows

Dataset shape: (53863, 10)
 Columns: ['published_date', 'open', 'high', 'low', 'close', 'per_change', 'traded_quantity', 'traded_amount', 'status', 'company_id']

Figure 9: Loading, Processing and combining the banks data into single one

5. Process Dates and Sort Data

Convert date column to datetime format and sort by company and date for chronological analysis.

```

D> # Convert published_date to datetime
data['published_date'] = pd.to_datetime(data['published_date'])

# Sort by company and date
data = data.sort_values(['company_id', 'published_date']).reset_index(drop=True)

print("Date conversion and sorting completed")
print(f"Date range: {data['published_date'].min()} to {data['published_date'].max()}")
print(f"First few rows:")
display(data.head())

```

(15)

... Date conversion and sorting completed!

Date range: 2009-06-25 00:00:00 to 2023-12-29 00:00:00

First few rows:

	published_date	open	high	low	close	per_change	traded_quantity	traded_amount	status	company_id
0	2010-09-18	102.0	122.0	118.0	120.0	NA	5386.0	0.0	0	ADBL
1	2010-09-19	120.0	120.0	118.0	118.0	-1.67	2646.0	0.0	0	ADBL
2	2010-09-20	118.0	119.0	116.0	118.0	0.00	2346.0	0.0	0	ADBL
3	2010-09-21	118.0	118.0	116.0	116.0	-1.69	7960.0	0.0	0	ADBL
4	2010-09-23	116.0	120.0	119.0	120.0	3.45	8470.0	0.0	0	ADBL

6. Save Combined Dataset

Export the processed combined dataset to a CSV file for use in regression models.

```

# Save to CSV
output_file = "combined_banks_dataset.csv"
data.to_csv(output_file, index=False)

print(f"Saved")
print(f"Combined dataset saved: {output_file}")
print(f"Total rows: {len(data)}")
print(f"Number of banks: {data['company_id'].nunique()}")
print(f"Date range: {data['published_date'].min()} to {data['published_date'].max()}")
print(f"Columns: {list(data.columns)}")
print(f"Saved")

```

(16)

... Combined dataset saved: combined_banks_dataset.csv

Total rows: 53,863
 Number of banks: 17
 Date range: 2009-06-25 00:00:00 to 2023-12-29 00:00:00
 Columns: ['published_date', 'open', 'high', 'low', 'close', 'per_change', 'traded_quantity', 'traded_amount', 'status', 'company_id']

7. Dataset Summary Statistics

Display descriptive statistics for numerical features in the combined dataset.

```

print("Dataset Summary Statistics")
print(f"Shape: {data.shape}")
display(data.describe())

```

(17)

4.4.1.3 Dataset Visualization

To achieve an answer to the question of how NEPSE stock price models were to be trained, the various exploratory visualizations are drawn of the data. The data were analyzed with the help of multiple visualizations in order to discover the distribution of the data and potential anomalies.

The following visualizations were included:

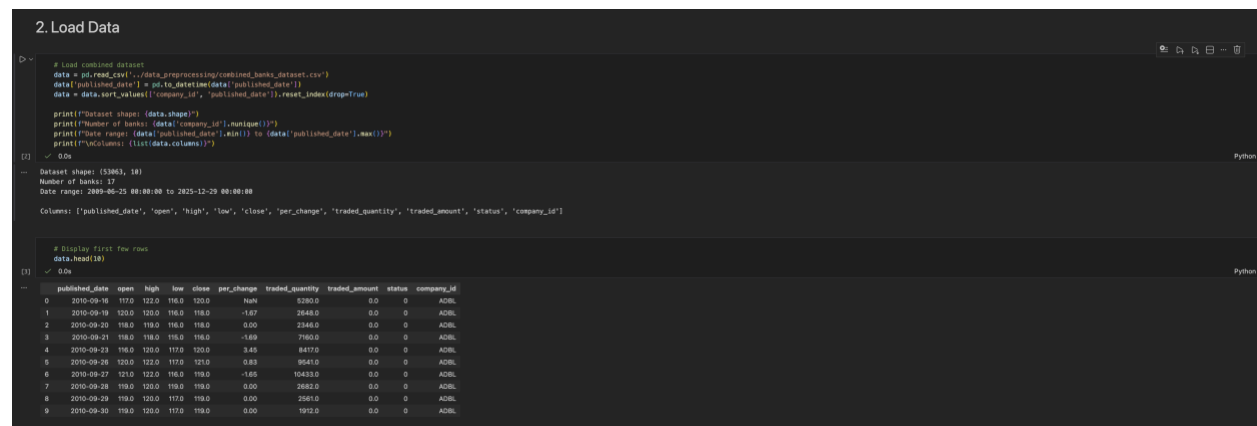

Figure 11: Data Loading

Figure 12: Data Distribution Visualization

Figure 13: Price Distribution

Figure 14: Visualization of closing price range of all banks

Figure 15: Average Closing Price Visualization over time

Figure 16: Closing Price Trends of 5 banks

Figure 17: Avg Trading Volume

Figure 18: Trading Volume vs Closing Price

Figure 19: Daily Percentage Changes

Figure 26: Model Training and evaluation (2)

4.4.1.6 Evaluation

- Set model to evaluation mode (disable dropout/batch norm training)
- Generate predictions on test set (12,411 sequences)
- Inverse transform predictions using `y_scaler` to original price scale
- Calculate regression metrics comparing predictions to actual test prices

4.4.1.6.1 Metrics Calculated:

- RMSE (Root Mean Squared Error): $\sqrt{\text{mean}((\text{actual} - \text{predicted})^2)}$
- MAE (Mean Absolute Error): $\text{mean}(|\text{actual} - \text{predicted}|)$
- R^2 (R-squared): $1 - (\text{SS}_{\text{residual}} / \text{SS}_{\text{total}})$
- MAPE (Mean Absolute Percentage Error): $\text{mean}(|\text{actual} - \text{predicted}| / \text{actual}) \times 100$

4.4.1.7 Final Test Results

Figure 27: Final Test Results

Figure 28: Final Tests Visualization

4.4.1.7.1 Key Findings:

- LSTM achieved best overall performance with lowest RMSE (7.30) and highest R^2 (0.9978)
- CNN performed competitively with slightly higher errors but faster training
- Transformer underperformed relative to LSTM/CNN, possibly due to:
 - Limited sequence length (60 days) not leveraging attention advantages
 - Smaller model capacity compared to optimal transformer configurations
 - Need for more data or longer sequences to benefit from self-attention

4.4.2 Tools and Technologies

4.4.2.1 Programming:

- Python 3.9+

4.4.2.2 Primary Development Platform: Google Colab

Google Colab was selected as the primary development environment for several key reasons. It provides free access to NVIDIA Tesla T4 GPU with 16GB VRAM, eliminating the need for expensive local hardware. The platform comes with pre-installed deep learning frameworks (PyTorch, TensorFlow), saving setup time and preventing version conflicts. The browser-based Jupyter notebook interface enables interactive development with immediate code execution feedback. Integration with Google Drive allows easy data storage and retrieval.

Figure 29: Using Cuda cores in colab

4.4.2.3 Libraries:

- Pandas (data handling)
- NumPy (numerical operations)
- Matplotlib/Seaborn (visualization)
- Pytorch (deep learning)
- Scikit-learn (preprocessing and metrics)

4.4.2.4 Environment:

- Jupyter Notebook
- Google Colab (GPU support)
- VS Code

4.4.2.5 Version Control:

- Git and GitHub
- Repository: <https://github.com/AmiksKarki/Stock-Price-Prediction>

4.4.2.6 Hardware:

GPU: NVIDIA Tesla T4

- Architecture: Turing
- CUDA Cores: 2,560
- Tensor Cores: 320
- Memory: 16 GB GDDR6
- Memory Bandwidth: 320 GB/s
- FP32 Performance: 8.1 TFLOPS
- Training acceleration: ~10-15x faster than CPU

System Memory: 12 GB RAM

- Sufficient for loading full dataset

- Handled batch processing without memory errors

Storage: ~100 GB in Colab environment

- Adequate for dataset (~13 MB) and model checkpoints

5 Conclusion

This paper considered the use of LSTM, CNN and Transformer model to stock market price prediction of closing prices of NEPSE. The common database was created in such a manner that the comparison of all the models would be equal. Formally speaking, LSTM engages the recognition of long-term trends, CNN gives consideration to short-term signals, and Transformers are high-performing using attention-based models.

Such new emerging markets as Nepal Stock Exchange will require the use of artificial intelligence forecasting to inform decision-making, support financial analysts and risk management. Although the presented work is merely a conceptual design of something rather than a real implementation outcome, the fact of the matter is that modern AI-based approaches could be employed to use in the process of solving real-life problems of finances prediction.

5.1 Evolution from Milestone 1

After getting a feedback of Mr. Binod Bhattarai, the scheme was changed to regression (actual price forecasting) rather than classification (price direction UP/DOWN). This became an advantage due to the following reasons:

- Better assessment and evaluation using regression measures.
- Stable and improved models.
- Streamlined company feature engineering.

5.2 Further Work

The path forward requires both deepening (improving current approach with better features, longer horizons, ensembles) and broadening (new techniques like RL, alternative data, hybrid models). The immediate focus should be:

- Using advanced models like Informer, LSTM-CNN hybrids, Temporal Fusion Transformers
- Test longer prediction horizons
- Implement ensemble methods

- Add datas such as sentiments, sector indices and macroeconomic indicators
- Trading Strategy Backtesting: Evaluate profitability with realistic transaction costs
- Study impact of data frequency (daily vs. hourly trading data)
